Guidelines

1. Decide what type of harmonization strategy to employ, taking into account that many harmonization efforts require some combination of strategies.
2. When deciding which variables to harmonize, create an initial plan and define clear objectives about what you want to achieve. The plan should include making all data conversions reversible.
3. Focus on both the variable and survey levels in the harmonization process.
4. Develop criteria for measuring the quality of the harmonization process. This includes testing it with users knowledgeable about the characteristics of the underlying surveys, the meaning of source variables, and the transformation of source variables into target variables.
5. Provide the widest range possible of data and documentation products about the entire harmonization process.

Further Reading
common questionnaire (see Sample Design and Translation). Also known as 'prospective,' this strategy is meant to a high degree of comparability. Some adaptations may occur for individual data collection sites, but the goal is to maintain comparability.

**Procedural steps**

1.1 Provide detailed specifications, protocols, and procedures for all aspects of the survey process. The different specifications (Data Protocol, Sampling, Translation, etc.) of the European Social Survey (ESS) and the Demographic and Health Survey (DHS) are good examples.

1.2 Decide which items to standardize.

1.3 Consider if variations may be necessary to account for site-specific interests. This can either be due to site research foci or resource limitations.

Consider output harmonization, also known as retrospective harmonization, when the survey collection primarily determined at the level of individual countries or cultures and there is minimal or no agreement on standardization.

**Rationale**

'Output' harmonization is implemented through two main strategies: 'ex-ante' and 'ex-post.' In practice, a study might utilize both strategies.

Ex-ante refers to measurements designed to be comparable and harmonized in data processing. When comparability has been considered during survey planning, the understanding of concepts, common goals, and specific targets can be established for the data collection process. The precise wording of the survey items may vary, but the items seek to capture the same concept (see Questionnaire Design and Adaptation).

The second variant is an ex-post strategy, by which statistical or survey data are deemed inferentially equivalent, made comparable after the fact through a conversion process. The items to be harmonized were not designed to be comparable, but are assessed and edited to achieve commonality. An ex-post strategy can be used in situations where existing repositories will be exploited for comparative research or where intensive early planning is not possible due to financial or policy constraints.

**Procedural steps**

1.4 Use an ex-ante strategy whenever possible. This enhances comparability since harmonization is addressed at the planning stage of each national data collection, as well as at the end of the process when creating harmonized files.

1.5 Implement an appropriate planning process.

1.6 Use an ex-post strategy only if no consideration regarding harmonization has been given by data collector at the start of data collection(s), but researchers later believe (e.g., because of common concepts or similar questions) that a harmonized data file can be produced through a conversion process to create comparable variables. The Integrated Public Use Microdata Series, International (IPUMS-I, available here) and the Integrated Fertility Survey Series (IFSS) are two such examples.

1.6.1 For any ex-post plan, ensure that data access, intellectual property, and any other ethical or legal issues are resolved for all intended source studies prior to beginning harmonization with the source in question. If study investigators have their data publicly available, it is advisable to obtain permission from them if...
to harmonize their data with other datasets. An individual study’s data use agreement may not apply, at
formal request to the respective research ethics or data access committees may be necessary.

1.7 Record all decisions about the 'conversion' process systematically. One option is to use two separate datab
record all work: a production database, which stores the original and harmonized materials, and a user’s dat
which provides the analysts access to the overall process.

1.8 Make provisions so that all data conversions can be traced back to the original data.

1.9 For any output harmonization technique, adopt a detailed 'data processing plan' that includes descriptions
the producer(s) of the harmonized data deal with the following:

1.9.1 Differences in study design, such as panel or cross-sectional design, and/or in mode of data collectio

1.9.2 Differences across studies with regard to what is measured (e.g., definitions of study population, con
variables).

1.9.3 Differences in how to measure (e.g., scale of measurement, wording and routing of questions, respon
asked).

1.9.4 Differences in how estimates are generated (imputation, weighting, or nonresponse adjustments).

1.9.5 Procedures used to create and define harmonized variables, including any harmonized weights calcu

Lessons learned

1.1 Input harmonization involves adherence to appropriately standardized methodologies throughout the survey
lifecycle. For example, the ESS seeks to collect high-precision data every other year using face-to-face interv
applies detailed sampling and fieldwork protocols, uses standardized translation protocols in all participating
countries, aims to achieve standardized response rates, adopts consistent coding procedures, and creates and
distributes well-documented datasets in a timely fashion. All of these procedures require greater organizationa
capabilities and resources throughout the planning and data collection stages. The results are transparent, high
and can produce more valuable public-use data files at the end.

1.2 Not all comparative research will be able to follow the same procedures, so it is important to decide which m
are best given the actual resources, the survey process structure, and the intended level of precision. In additio
creation of such common standards and their implementation at the local level requires considerable expertise
may not be available in all 3MC contexts. The Generations and Gender Programme is a large longitudinal 3M
survey that studies relationships between parents and children and also between partners. It is conducted using
paper-and-pencil instrument (PAPI) as well as computer-assisted interviewing (CAPI), and seeks to follow co
harmonization practices. While much harmonization work occurs centrally, individual country teams are urge
to follow certain procedures to improve comparability. This method requires considerable coordination among
components of the survey teams at all levels.

1.3 Flexibility can be designed. Research sites in different countries may not be able to follow the same procedu
it is important to decide which methods can be adapted and define procedures for adaptation given the actual
resources, the survey process structure, and the intended level of precision. For example, the Malaria Indicato
is an optional component that can be conducted in the context of the Demographic and Health Survey with or
biomeasure collection. The creation of such common standards and their implementation at the local level req
considerable expertise, which may not be available in all 3MC contexts.

1.4 In a working paper, Roland Gunther describes in detail the harmonization efforts surrounding the European
Community Household Panel (ECHP), an exemplary use of input harmonization. The survey was designed fi
beginning to use input harmonization with its design of uniform questionnaires as well as detailed definitions, procedures, and models to make comparability across nations easier. After the first phase of the project, a few countries decided to cease collecting national samples for the ECHP and instead conduct their own national surveys, resulting in the need to do ex-post harmonization. Those doing the harmonization work learned that this kind of post-harmonization was resource-intensive and required staff experienced in both the original source and target formats of the ECHP framework. They also had to know in detail how their national questionnaires differed. Problems included concepts heavily affected by national contexts as well as differences in scales of measurement variable coding schemes, and definitions of concepts. Solutions to such problems were often found through decisions about recoding, combining, or collapsing variables, and almost never through estimation techniques.

1.5 These harmonization strategies are almost never applied exclusively on any single statistical or survey data collection. Depending on specific cultural and national characteristics, data producers should consider strategies that will enable them to collect their data in the most efficient manner. In some situations, they may want to combine strategies. For example, data producers may start with an input harmonization plan, but should be prepared to use ex-post output harmonization to account for differences across cultures. For example, the Demographic and Health Surveys has standardized instruments, but also provides a Standard Recode Manual.

1.6 Health researchers in particular emphasize the importance of ex-post output harmonization. Because of the copious amounts of data generated by national governments and individual investigators which affect public health policies, the desire to pool cases cross-nationally to increase sample sizes is highly desired. To insure comparability, investigators involved in this process developed a very systematic approach to harmonization and encouraged its use through relevant research communities.

1.7 Output harmonization projects also generate copious amounts of metadata describing the source variables and the entire harmonization process. This new metadata provides researchers with opportunities to use this information and create additional linkages. For example, individual variables can be grouped into substantial categories or concepts to enhance the analytical power of a new harmonized dataset.

1.8 An innovative approach to ex-post harmonization is the survey data recycling (SDR) project proposed by Slomczynski and Tomescu-Dubrow (2019). SDR aims to create an integrated database drawing from multiple and non-survey data sources. Central to the SDR concept is the goal of enabling researchers and data users to identify methodological biases and potential errors in the survey data by providing two types of metadata: control variables related to survey quality and those related to the ex-post harmonization process. This way, researchers can use control variables to assess, control, or possibly assign varying weights to account for the effect of these variables when 'recycling' rather than throwing out data of varying quality (Slomczynski & Tomescu-Dubrow, 2019).

2. When deciding which variables to harmonize, create an initial plan and define clear objectives about what you want to achieve. The plan should include making all data conversions reversible. **Rationale** Creating a harmonization plan from the beginning of the project allows data producers to document all of their decisions at the time they are made. If case errors occur or are identified by users at a later time, all data conversions should be reversible. **Procedural step**

2.1 Before conducting fieldwork, consult with experts or an advisory committee on a systematic design process with methodology groups to investigate comparability issues. If pre-fieldwork coordination is not possible, form an advisory committee of researchers knowledgeable about the subject matter at the beginning of the harmonization process, if possible, and consult with them regularly.

2.2 Show the advisory group results of the harmonization process at different points in the process to allow for changes in the rules used to create new variables.
2.3 Consider establishing a testing group of users knowledgeable about the subject matter, separate from the harmonization process, who provide feedback on the analytic usefulness of the data before they are released.

2.4 Implement a systematic conversion creation process with appropriate quality controls.

2.5 Identify and become familiar with software tools that facilitate a comparison of variables from different sources to determine if and how these could be harmonized. Such tools often work from a common database containing all the information about each variable.

2.6 Establish partnerships with producers of harmonization tools. This may be more beneficial than creating new tools often requires costly programming efforts.

2.7 Where software tools are unavailable or impractical, use manual comparisons in making harmonization decisions and consult with substantive and methodological experts in doing so.

2.8 Identify and become familiar with interactive documentation tools that allow for proper and transparent documentation. For example, Opal is a tool designed to harmonize epidemiological data.

Lessons learned

2.1 Realize that not all concepts measured in the survey process are equally amenable to harmonization efforts. For example, cross-national harmonization of the number of births and marriages is a far easier task than comparing divorce rates where local laws, customs, and data collection methods may differ substantially. Other concepts, such as international population migration, may not lend themselves to harmonization at all, or only at the most basic level due to a lack of precise definition and great variety in measurement criteria. Three characteristics that could impact harmonization potential are (i) the relative importance to the research intending to use the harmonized items, (ii) the individual the item targets (e.g., the participant, the participant’s family members), and (iii) the period of time which the variable refers to.

2.2 Good decision-making about the harmonization process will benefit from the use of software tools, as well as input from a diverse group of survey researchers who can offer advice on various procedures and techniques to use in producing harmonized files. The ISSP Data Wizard was used by the International Social Survey Programme (ISSP) as one of the first tools developed to support procedures that were previously performed manually to harmonize data at the cross-national level. The tool offered rule-based checks, automation of partial steps, and the visualization of certain conditions to make the harmonization process more efficient, easier, and less susceptible to mistakes.

2.3 The European Values Study (EVS) formed a number of work groups, both before and after fieldwork. The goal on the one hand was to set standards at an early stage, and on the other to consolidate and merge data which had been cleaned by participating national survey teams. This project produced an integrated source questionnaire and a set of equivalency tables to assist secondary researchers. The project website makes all of this information easily accessible. These processes and products provide critical information to secondary users of these data.

2.4 The DataSchema and Harmonization Platform for Epidemiological Research (DataSHaPER) is one potential tool for output harmonization. Fortier’s 2011 paper showed that using the DataSHaPER across 53 studies, 64% of “essential” constructs from those selected could be harmonized completely or at least “partially.” This estimate of the most conservative criteria, and evaluation of harmonization potential would likely improve this statistic. A version of this tool is also available.

3. Focus on both the variable and survey levels in the harmonization process. Rationale Harmonization efforts concentrate on comparing and integrating information involving specific variables across data files. However, it is e
important to consider the overall characteristics of the surveys that make them good candidates for harmonization, a report the decisions involving this process to end users. **Procedural steps**

3.1 Recognize the different aspects involved in converting source variables, which might include variable conceptual scales of measurement, into target variables. The concept of citizenship, for example, presents significant challenges to researchers who want to investigate this topic.

3.2 Describe similarities and differences between the source variables and the target variables, including discussion about universe statements, question wording, coding schemes, and missing data definitions. There may be an unavoidable loss of information resulting from harmonization, such as if a variable that was continuous is being harmonized into a categorical variable.

3.3 Consider file-level attributes when creating the harmonized data file, including how survey weights, imputation procedures, variance estimation, and key substantive and demographic concepts will change in the process.

3.4 Pay particular attention to sampling designs and data collection methods in making assessments about the comparability between different surveys. See **Survey Quality** for a discussion of how quality profiles can be developed and used to assess comparability in a 3MC survey.

**Lessons learned**

3.1 Data producers must recognize the degrees of individual item or variable persistency when creating questionnaires and collecting data. Item persistency over time is very important in generating harmonized data files. There are considerable differences, for example, between an 'absolute' persistent variable, such as 'country of birth,' and a persistent variable, such as 'country of citizenship.' The concept might mean different things in different countries and be subject to change, and could be reported validly for multiple countries by some respondents.

3.2 Quota sampling destroys comparability (1). Harmonization will not make data from quota sampling comparable with data gathered via probability sampling. The ISSP is an example of a 3MC survey program that abolished quota sampling.

3.3 The European Social Survey (ESS) provides detailed insight into weighting issues and makes this information available. See the ESS data site for each survey round for the latest version.

3.4 The created a harmonized data file from three comparable surveys on mental health. Data producers created a pooled weight for the harmonized file based on race/ancestry groupings and on the geographic domains of the sampling frames of each individual survey. Understanding the specific characteristics of each input file was an essential part of creating a harmonized output file. All of this information was provided to users in a comprehensive explanation of the original and harmonized weights.

3.5 Zieliński, Powalko, and Kołcyńska (2019) distinguish between three strategies for harmonizing weights: (1) recalculating weights using external sources of information; (2) harmonizing the data instead of the weights; and (3) including weight components and the quality indicator of weights as independent variables in models to account for the original weight components. The authors analyzed 1721 national surveys in the context of the Survey Data Recycling (SDR) project and concluded that only about 60% of the included surveys provided statistical weight information on how the weights were constructed was reported for 25% of the surveys (Zieliński et al., 2019).

4. Develop criteria for measuring the quality of the harmonization process. This includes testing it with users knowledgeable about the characteristics of the underlying surveys, the meaning of source variables, and the transformation of source variables into target variables. **Rationale** Researchers may analyze harmonized files in...
and unexpected ways. It is crucial to provide them sufficient information about the concepts and definitions presented, the assumptions underlying the decisions made in their construction. **Procedural steps**

4.1 Devise procedures to judge the quality of the harmonized outputs based on such quality criteria as consistence, completeness, and comparability.

4.1.1 Consistency can be judged by comparing the results from multiple independent efforts of harmonizing data; completeness is assessed based on the degree to which the original information is preserved in harmonized data; and comparability is the degree to which the harmonized outputs can accurately report important social or economic concepts over time or between countries or cultures.

4.1.2 The Statistical Office of the European Communities (EUROSTAT) proposed the following set of quality criteria when reporting statistics which also apply to harmonization outputs (Database of Integrated Statistical Activities, 2014; Joint UNECE/EUROSTAT Work Session on Statistical Data Confidentiality, 2009):

- Relevance of the statistical concepts.
- Accuracy.
- Topicality and timeliness of the dissemination of results.
- Accessibility and clarity of the information.
- Comparability of the statistical data.

4.1.3 Strictly speaking, these traits apply to official statistical data. However, many of them would apply equally to academically produced survey data, particularly those regarding the comparability of social, economic, and demographic concepts in a 3MC context and the accuracy of estimates.

4.2 Be prepared to modify and update harmonized datasets after public release based on comments from the research community if errors are uncovered, or if certain variables need further explanation.

4.3 Prepare presentations at social science research conferences that describe the harmonization process to potential users.

**Lessons learned**

4.1 The usefulness of well-harmonized data is clearly recognized by many international organizations. The United Nations Economic and Social Council recognized the importance of harmonizing environmental data collection activities in order to produce comparable indicators on the environment and its relationship to the economy. It determined to bring the System of Environmental-Economic Accounts (SEEA) to an international statistical standard. The SEEA now provides the first international standard for environmental-economic accounting (see here for information).

4.2 In the context of the Harmonization Project, a comparative project examining the relationship between demographic and political protest by harmonizing data from 1721 national surveys contained in 89 waves of 22 international projects (see Slomczynski and Tomescu-Dubrow (2019) for extensive description), Oleksiienko, Wysmulek, and Vangeli (2019) analyzed the edited data for seven target variables, ranging from socio-demographic variables such as respondent age and years of schooling to substantial variables like trust in various government entities. They developed the following classification of processing errors: illegitimate variable values, as defined by codebook metadata; misleading variable values due to inconsistent or incomplete coding schemes; contradictory values between different metadata sources; variable value discrepancy between different metadata sources; and variable value labels not defined in any documentation source. In their analysis, Oleksiienko et al. (2019) found that at least one of the five processing errors occurred in the source variables in the cross-national surveys under scrutiny.

4.3 Also using data from the Harmonization Project (see Slomczynski and Tomescu-Dubrow (2019) for extensive description), Kołcyńska and Slomczynski (2019) proposed to use item metadata such as survey question prop.
5. Provide the widest range possible of data and documentation products about the entire harmonization process.

Rationale: Regardless of whether utilizing input or output harmonization as a strategy, all aspects of the survey planning, collection, and dissemination process should be considered when producing harmonized data files or creating accompanying documentation. Users should have access not only to the harmonized end result, but also to detailed information about the steps taken by the producers, as well as source materials, in order for them to fully understand what decisions were made during the entire process.

Procedural steps

5.1 Define the elements of the harmonization process and start documenting it from the beginning in order to ensure that all decisions are captured even before a definite plan to produce a public-use data file exists.

5.2 To the greatest extent possible, document each target variable with information from all source variables, transformation algorithms, and any deviations from the intended harmonized approach.

5.3 If possible, provide users with access to the original data files used in producing the harmonized file. If direct access to original data is not permissible due to confidentiality concerns, implement procedures to assist users in producing check-backs or re-transformations. Also consider implementing some form of restricted-use data agreement to allow access under controlled conditions.

5.4 Prioritize providing users with the code or syntax used in creating new variables for the harmonized file.

5.5 Provide users with as-complete-as-possible documentation, including crosswalks, which describe all the relationships between variables in individual data files with their counterparts in the harmonized file. An interactive, Web-based documentation tool is often the best way to present such documentation.

5.5.1 Include original questionnaires and information about the data collection process whenever possible.

5.6 Report on as many of the following elements of the data lifecycle as it applies to the particular harmonization process:

Study Design and Operational Structure:

5.6.1 Project planning.

Sample Design, Questionnaire Design, and Instrument Technical Design:

5.6.2 Sampling frame.

5.6.3 Sample size.

5.6.4 Sample design.

5.6.5 Duration of the field period.

5.6.6 Instrument construction and design.
Adaptation of Survey Instruments and Translation:

5.6.7 Translation and adaptation.

Data Collection:

5.6.8 Mode(s) of interview.

5.6.9 Respondent followup if panel survey.

5.6.10 Data collection methods (See Data Collection: Face-to-Face Surveys, Data Collection: Telephone Surveys, Data Collection: Self-Administered Surveys, and Survey Quality).

Data Processing and Statistical Adjustment:

5.6.11 Editing.

5.6.12 Item nonresponse.

5.6.13 Unit nonresponse.

5.6.14 Any special treatment given to demographic and country-specific variables.

5.6.15 Sample weights.

5.6.16 Variance estimation.

5.6.17 Data production, including both planned and ad-hoc decisions implemented during variable conversion.

5.6.18 Documentation production.

Data Dissemination:

5.6.19 Dissemination.

This list is based on documentation provided in the Integrated Health Interview Series (IHIS). The IHIS is designed to provide an assortment of variables from the core household- and person-level files from the National Center for Health Statistics’ seminal data collection effort on the health conditions for the U.S. population from 1969 to the present. It provides extensive user notes and FAQ pages to describe how their harmonization project coped with several of these components.

5.7 Consider archiving the original and harmonized data with a trusted data archive to ensure continued availability of all data and documentation files and long-term preservation. See Data Dissemination for additional discussion regarding archiving.

Lessons learned

5.1 The Eurobarometer Survey Series, in operation since 1973, now includes several dozen cross-sectional surveys which have been harmonized into single cross-national files before being made available to researchers. These surveys are released initially with basic information about each study and the characteristics of all variables, and then further processed by the social science data archives, led by German Social Sciences Infrastructure Services. These archives include variable frequencies, more complete documentation, and online analysis services for researchers. Such partnerships between data producers and social science data archives encourage long-term preservation, enhance access, and make it possible to continually improve services to the research community.
5.2 Some harmonization projects have gone to great lengths to describe their procedures in specific detail. For example, the Multinational Time Use Study (MTUS) has a User Guide and a comprehensive description of its coding procedures used in creating its harmonized data file. Similarly, the Generations and Gender Programme (GGP) United Nations Economic Commission for Europe Population Activities Unit (UNECE-PAU) provides report guidelines about how the organization implements its harmonization decisions. These projects provide transparency to both creators and users of these data and serve as an example for others to follow.

5.3 As part of the Harmonization Project (see Slomczynski and Tomescu-Dubrow (2019) for extensive description), Kołczyńska and Schoene (2019) propose a schema for evaluating survey quality through the accompanying descriptive documentation. Indicators cover the following stages of the survey lifecycle and indicate the presence or absence of a particular type of information: sampling, response rate, questionnaire translation, pretesting, and fieldwork control. The authors conclude that long-standing cross-national surveys since the 1990s have placed high importance on documentation, which consequently led to increased documentation quality. Kołczyńska & Schoene (2019) found higher levels of documentation within European cross-national surveys compared to those in America, the Caucasus, and the Middle East (Kołczyńska & Schoene, 2019).
